

Scheduler and Survey Strategy

Peter Yoachim

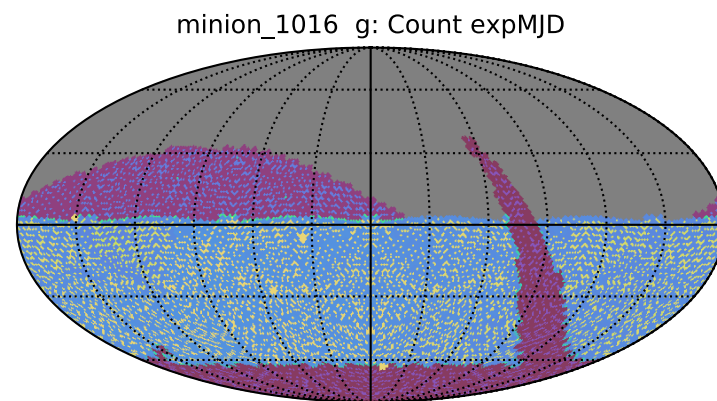

University of Washington

Ways folks try to schedule telescopes

- Have proposals that list observations to be done, ranked by a TAC
 - Can manually select programs to execute (most observatories)
 - Use a greedy algorithm to select observations on the fly (previous OpSim)
 - Optimize the schedule using Integer Programming (ZTF, LCOGT)
- Just scan the sky in a set pattern (AltSched, Rothchild et al 2019)
- Make a configurable/trainable AI that picks what to observe
 - Markov Decision Process (Naghieb et al 2019)

Opsim circa 2017

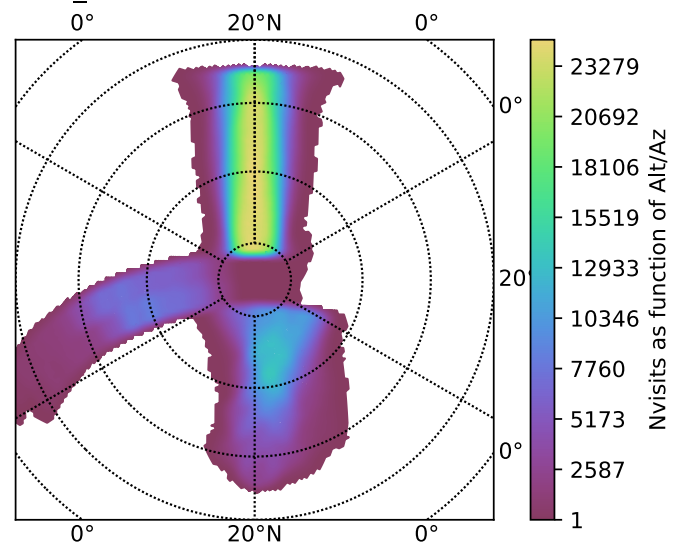

- Meets SRD
- Survey footprint adjustable
- Unstable behavior and often collapses to airmass limit
- No spatial dithering
- Tough to modify proposals, debug behavior

Rothchild et al, AltSched 2017

- Very fast to run
- Effective dithers
- Well sampled light curves
- No recovery from weather/downtime
- Points at the moon sometimes
- Tough to modify, can't really change survey footprint

roth_1 : Nvisits as function of Alt/Az

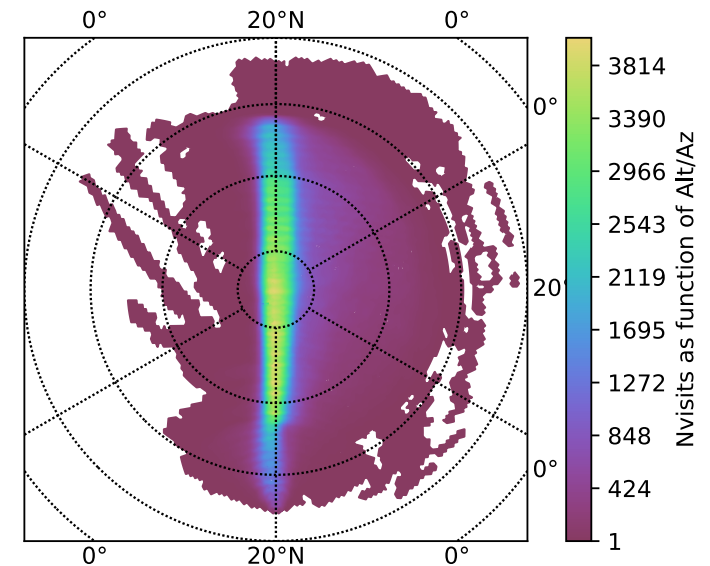

opsim g: Count_g

Naghib et al, Feature Based Scheduler 2017

- Shows promise on balancing conditions and survey footprint
- No dithering
- Observing at zenith
- Not modular code

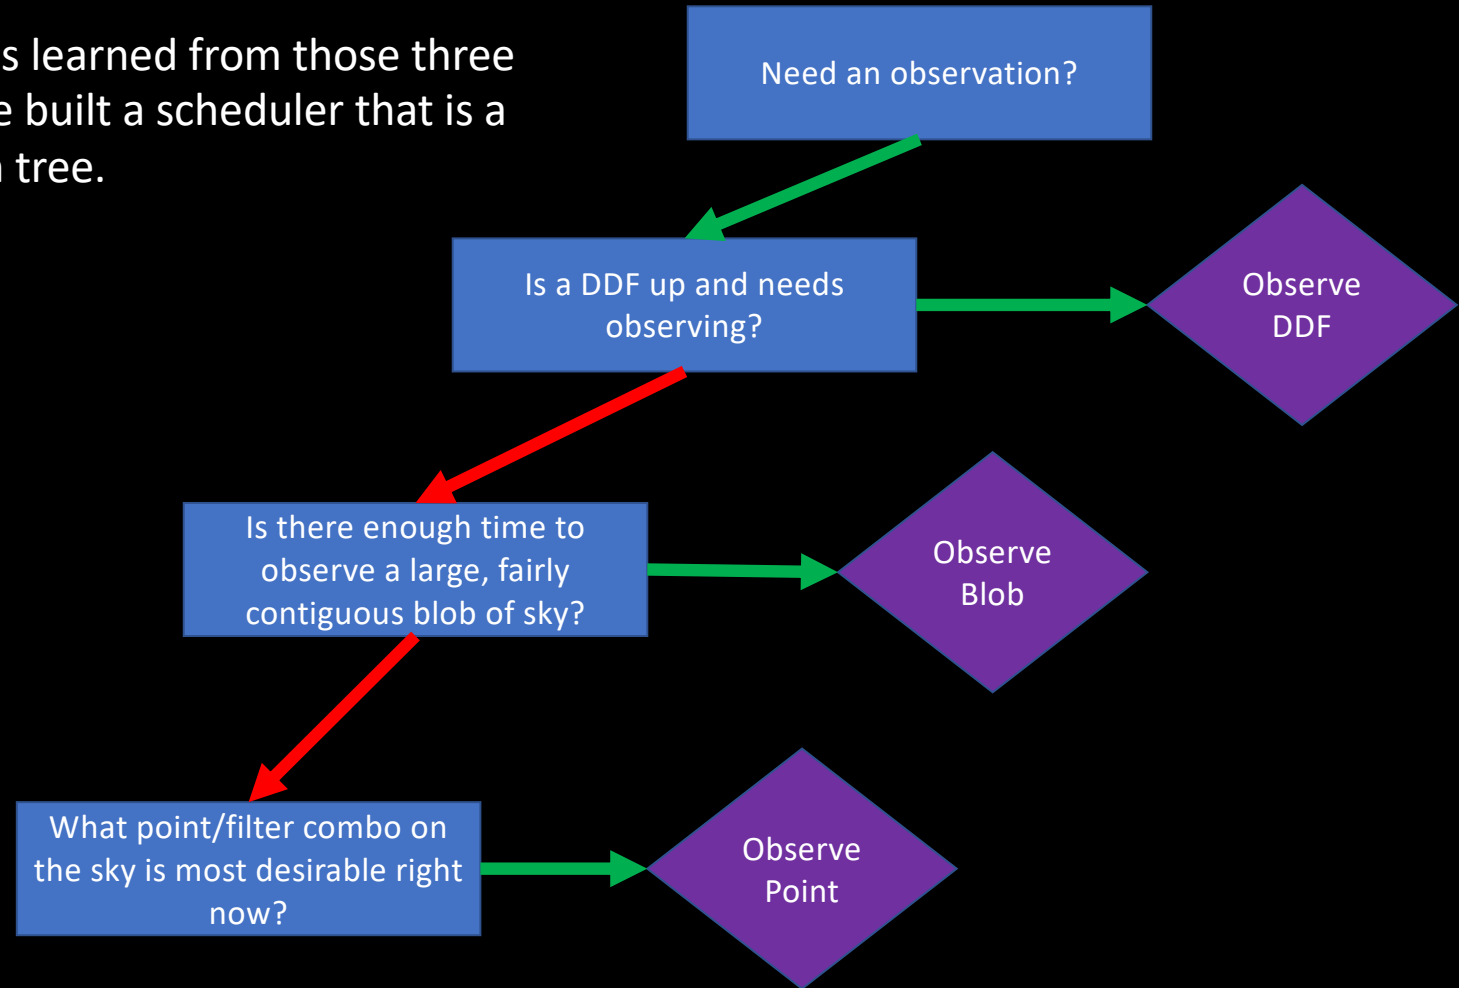

opsim : Nvisits as function of Alt/Az

opsim : Count_all

Taking the lessons learned from those three schedulers, we've built a scheduler that is a modular decision tree.

The Markov Decision Process
how we pick non-DDF
observations

Features i.e. the
current state
(MJD,
Skybrightness map,
Observing history)

Basis Functions

Reward Function
(linear combo of
Basis Functions)

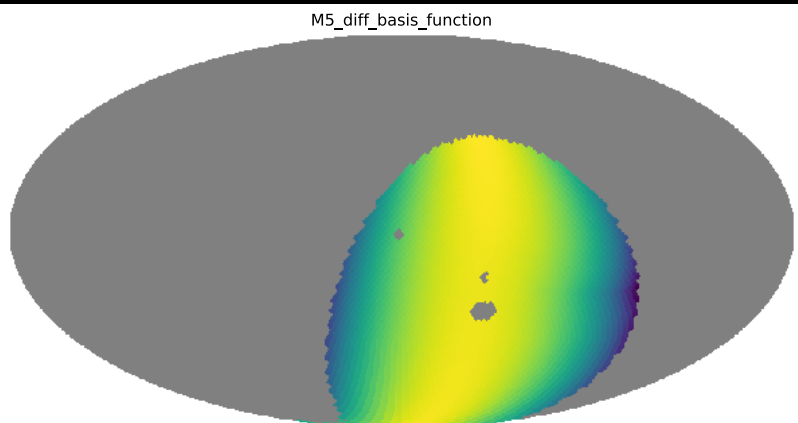

Decision Function

Basis functions

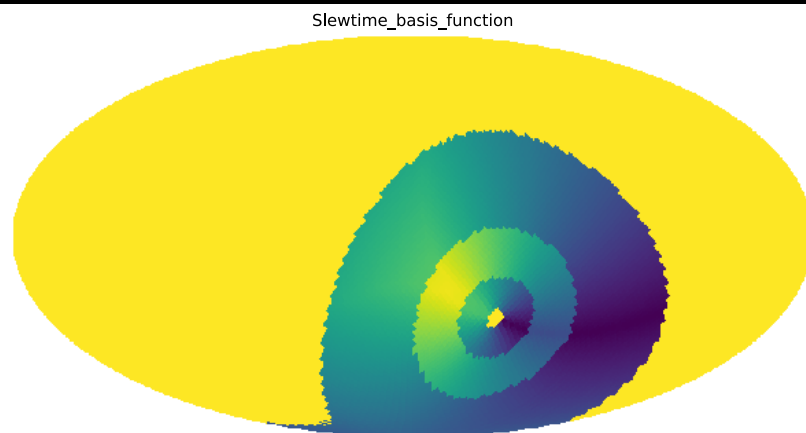

- Calculated on nside=32 HEALpix grid (1.8 degree resolution)
- Slewtime
- Survey progress (normalized) minus desired footprint
- Point source 5-sigma limiting depth (from skybrightness, airmass, seeing, filter) MINUS 5-sigma depth in dark time on the meridian. This is, how many magnitudes of penalty is it to observe a spot now versus waiting for it to be optimal conditions. Works great for making spatial selection and filter selection (currently assuming 1-mag of depth in one filter is worth the same as a mag of depth in another).

The Basis functions

M5_diff_basis_function

Slewtime_basis_function

Target_map_basis_function

R-band basis
functions, paused a
few days into survey

Moon_avoidance_basis_function

Zenith_shadow_mask_basis_function

Moon and zenith mask basis functions

Reward Function

-7.81222

Reward

2.34138

Cropped Reward

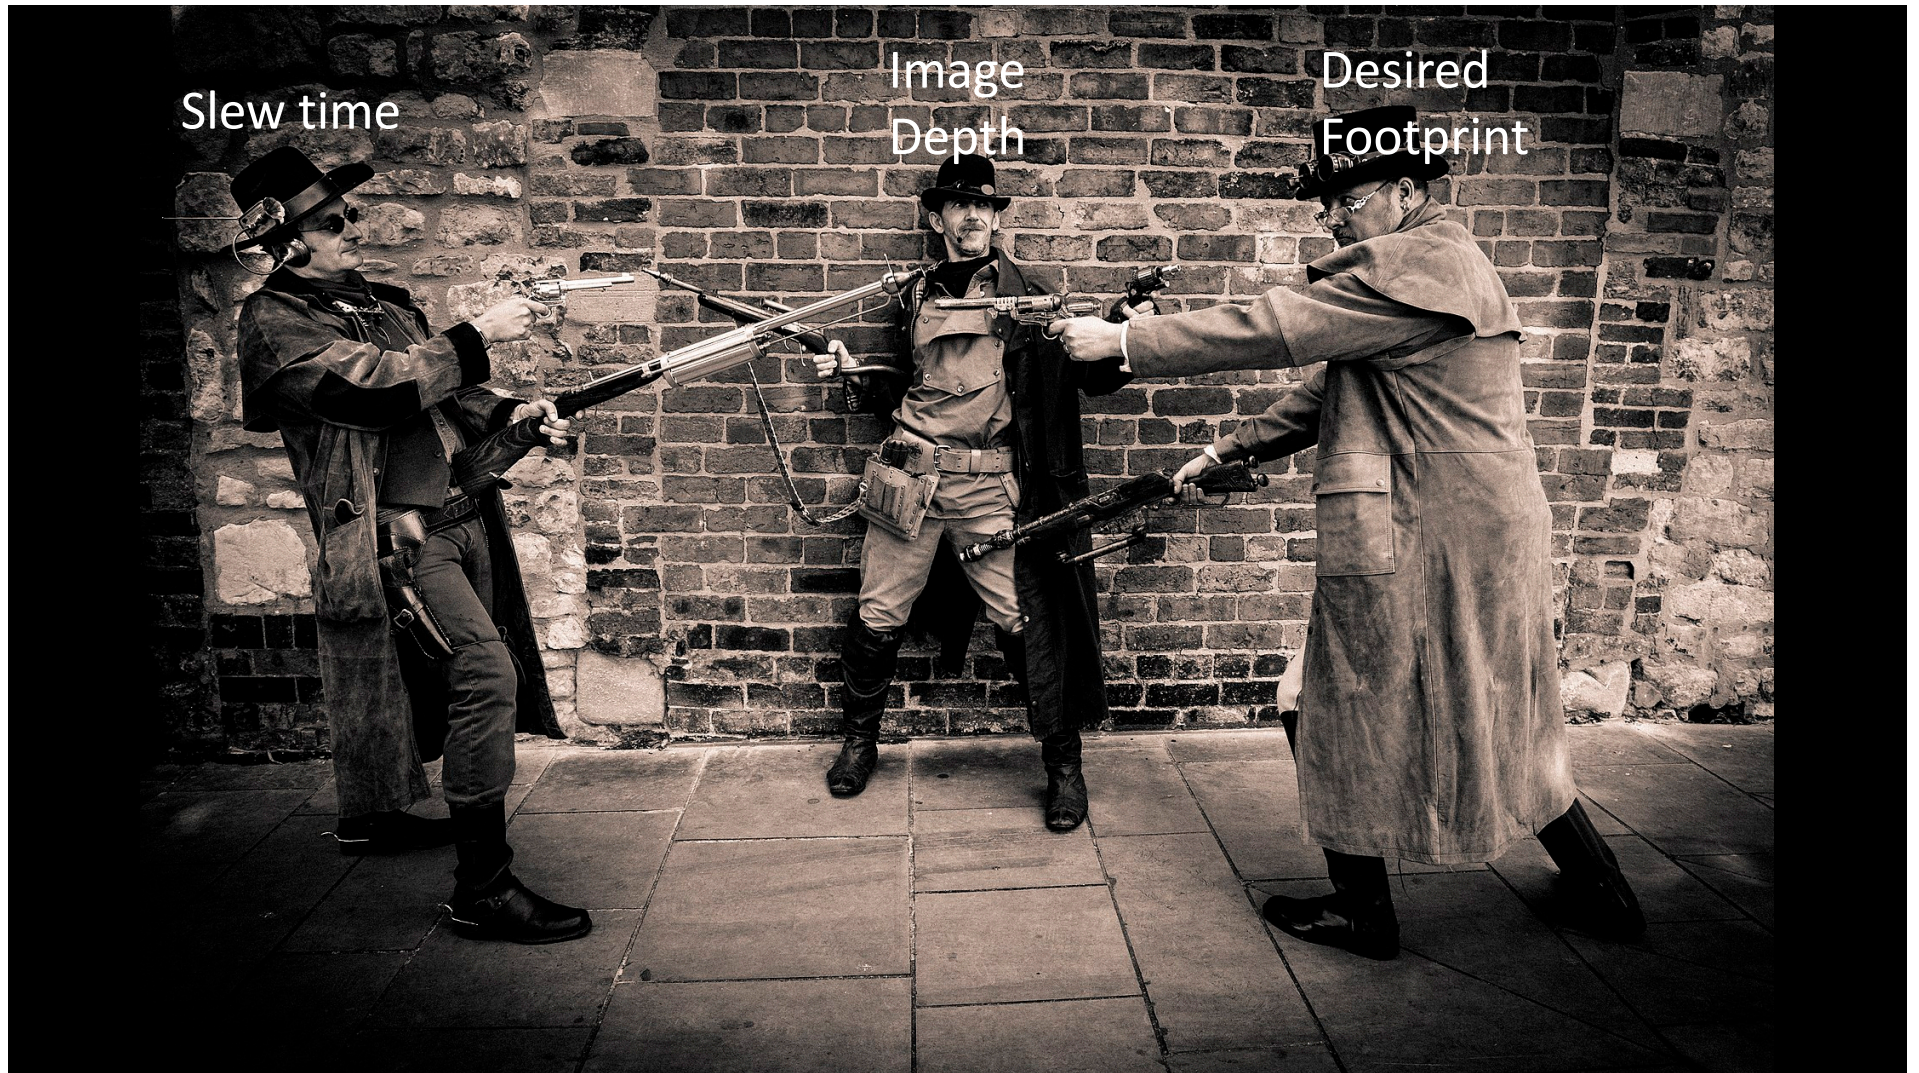

HEALpix to pointing mapping randomized each night.
Project to plane and solve traveling salesman
List of observations get rotator angle set, then added to the queue

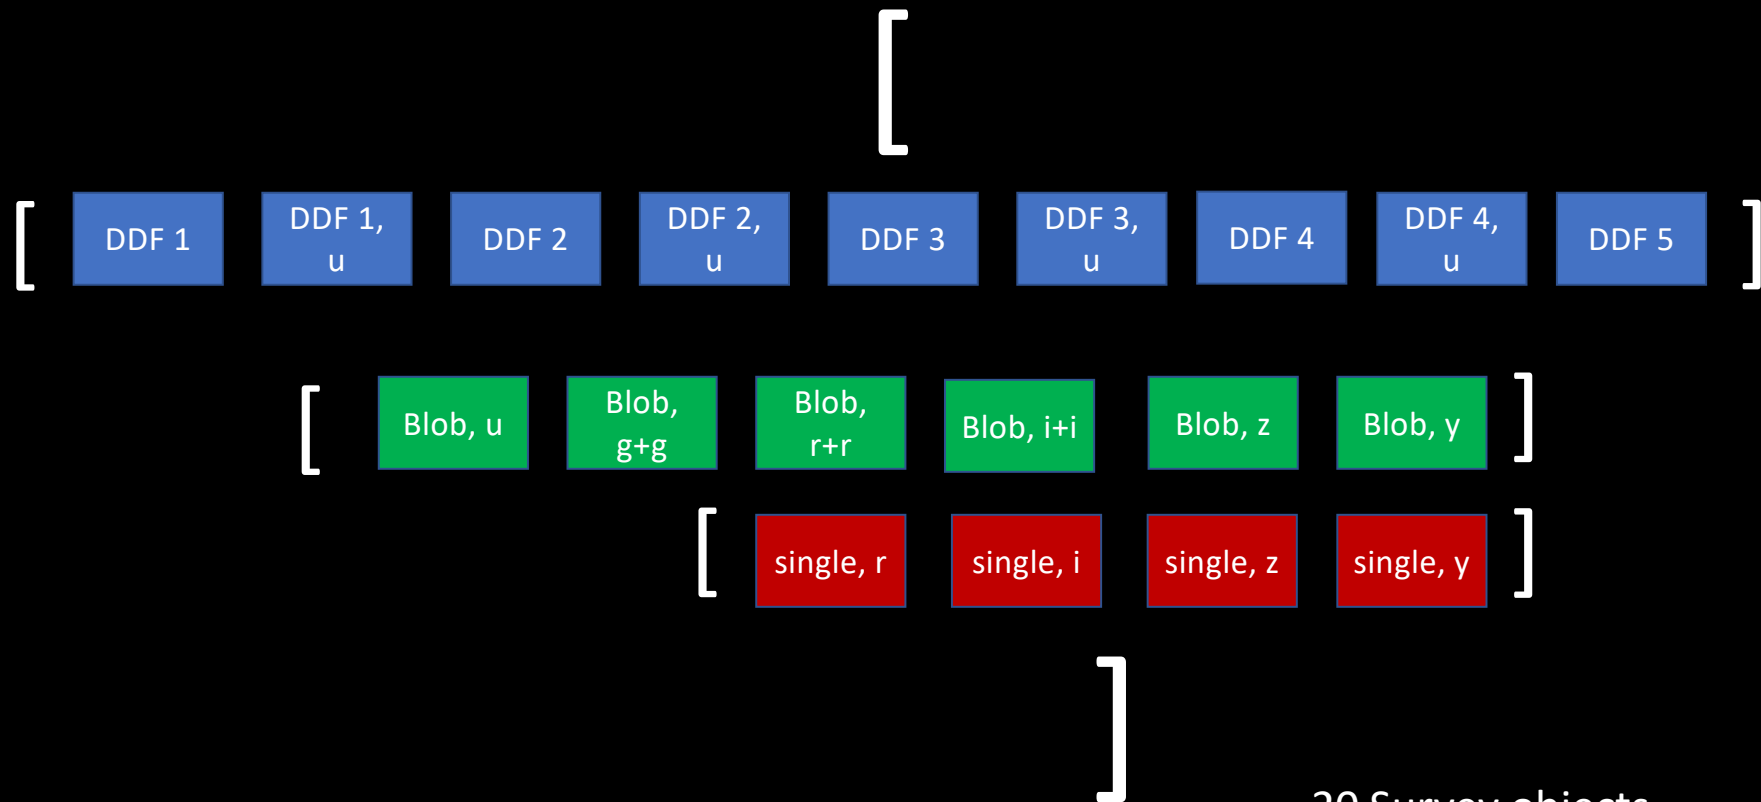

Slew time

Image
Depth

Desired
Footprint

Our “scheduler” is a modular object oriented decision tree

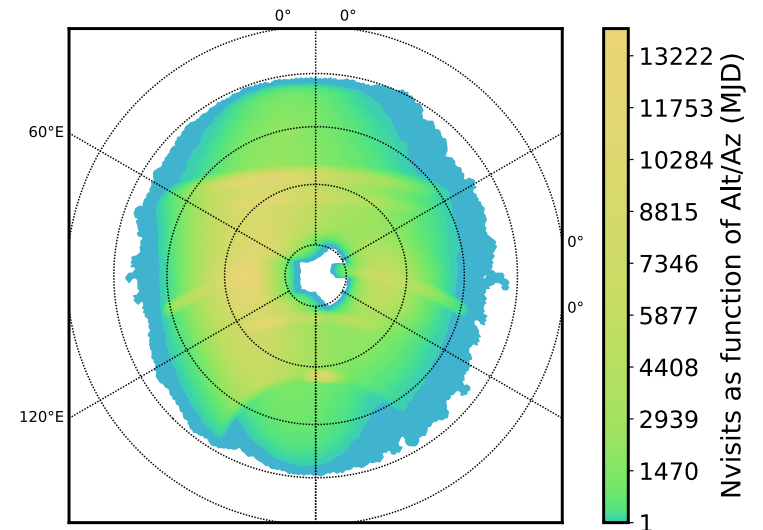

20 Survey objects

New Baseline

- Can set arbitrary survey footprint
 - Spatial dithering
 - Observations near meridian (but avoids moon and zenith)
 - Object oriented python, so easy to modify behavior
 - Small number of free parameters to train to optimize behavior
-
- No fixed sky tessellation (i.e., no fields)
 - No master list of observations to execute
 - No “global” optimization (this is a trained AI)
 - No config file, build scheduler object with ~200 lines of python

baseline_1exp_pairsmix_10yrs : Nvisits as function of Alt/Az

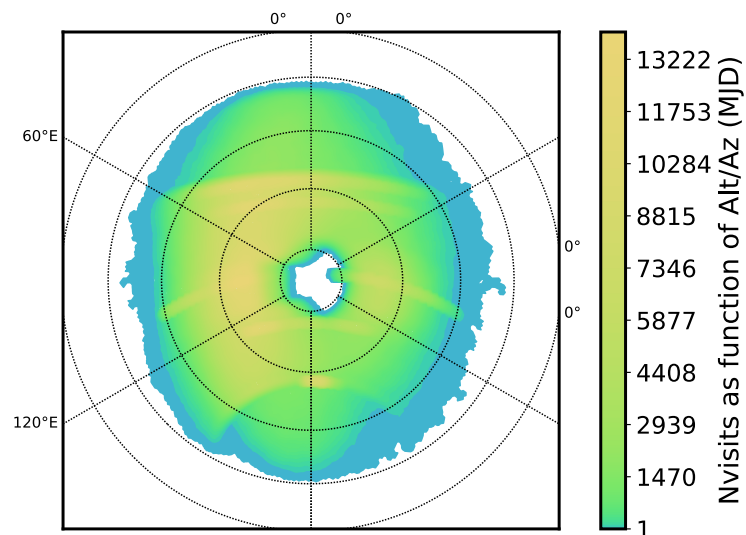

baseline_1exp_pairsmix_10yrs : Count observationStartMJD

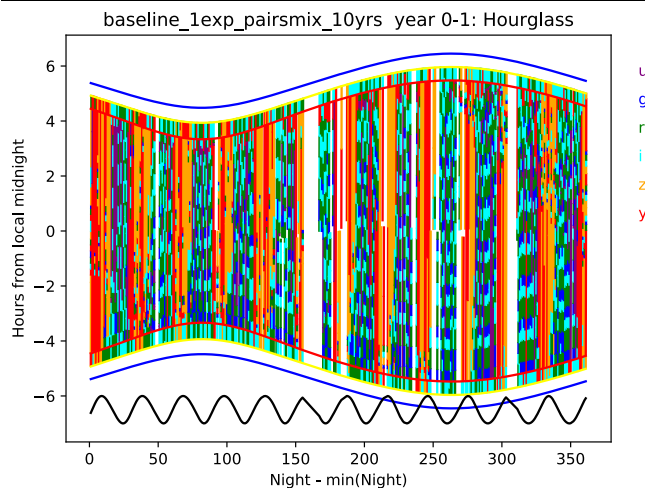

- Properly dithered final footprint
- Observations at reasonable hour angles
- Red filters in bright time
- No pointing at moon, no pointing at zenith
- Open shutter fractions 71-80% (max would be ~84% with no filter changes)

The scheduler is (finally) not doing anything obviously wrong

baseline_1exp_pairsmix_10yrs : Nvisits as function of Alt/Az

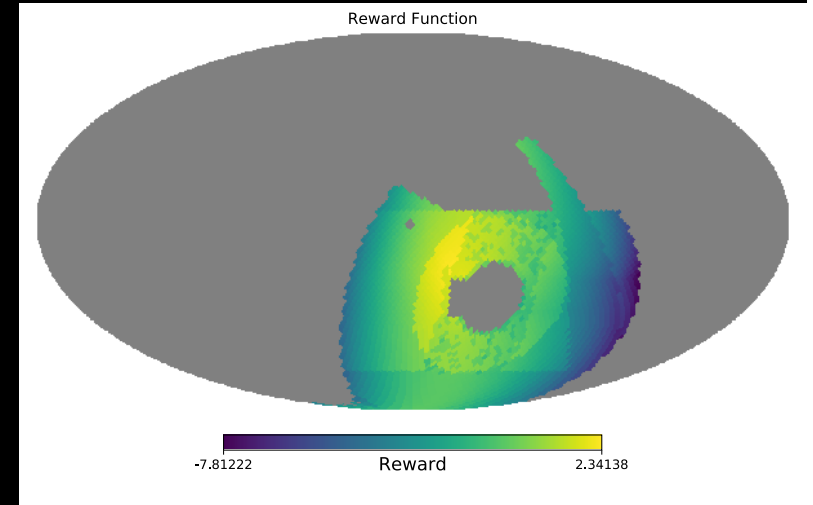

baseline_1exp_pairsmix_10yrs : Count observationStartMJD

We are leveraging

- The reward function changes slowly
- No one has demanded high-precision temporal scheduling on observations (observations should be paired, but with 15-30 minute gaps).
- No strong temporal constraint on when DDFs get observed

If we wanted to spend most of the time doing DDF-like observations, it would probably be better to use integer programming for scheduling. Now we have ~1 DDF sequence per night, so little to no penalty treating them as interrupts.

Stuff we did the SAC asked for

- Pairs in same or different filters
- 1x30 or 2x15 visits
- Footprint variations (9 different ones)
- Presto color (g+i+pause+g)
- Vary u-band filter loading
- 1s or 5s exposure sky coverage
- Rolling cadences (13 variations)
- Dithered DDF (spatial)
- DESC DDF
- Target of opportunity
- Stability tests

Bonus Experiments

- Pathological footprint
- Variable exposure time
- AltSched like behavior
- Camera rotator dithering
- Smarter rolling cadence

Still in the queue

- AGN DDF
- Akari and WFIRST/Euclid DDF experiments
- Bulge and low galactic latitude variations
- LMC/SMC mini-surveys
- Twilight NEO survey
- Twilight DCR
- Mini-surveys in the North
- Season extension (not super well defined)
- Anti-alias timing (tough to do, is it really a problem?)

Issues

- **Fixed** optimistic weather downtime, we now match SOAR and Gemini South
- DDF logic probably too strict, v1.2 released runs couldn't catch up when they fell behind (e.g., downtime during season). **Mostly fixed**, can re-run DDF experiments in next version release
- Probably need to enforce full sky coverage every year (for difference imaging templates and ubercal)
- Add bright planet avoidance (explicitly)
- Soften moon avoidance limit?

“Why didn’t you simulate what we wanted?”

- White Paper → SAC → people writing code
- Took artistic liberties to ensure simulation could still meet SRD, or just to make it faster to code
- Some white paper ideas are easier to put in the Markov Decision Process framework than others
- We made 87 sims and still aren’t through the list, there hasn’t been time to check that simulations are exact matches to what was requested

Please look at what we have released, and give us feedback on how it looks, we can make more iterations

Baseline-like sims

- 1x30s snaps in a visit
- 2x15s snaps in a visit
- g+g, r+r, i+i pairs
- g+r, r+i, i+z pairs

*1x30s snap, mixed filter pairs
as the “baseline” behavior for
the rest of the simulations*

Footprints

- 8 different survey footprints

gp_heavy10yrs : Count observationStartMJD

Galactic Plane like WFD

newB10yrs : Count observationStartMJD

Decrease Galactic anti-center,
extend WFD, cover all of north

bluer_footprint10yrs r: Count observationStartMJD

big_sky_nouiy10yrs r: Count observationStartMJD

gp_heavy10yrs r: Count observationStartMJD

stuck_rolling10yrs r: Count observationStartMJD

big_sky10yrs r: Count observationStartMJD

newA10yrs r: Count observationStartMJD

newB10yrs r: Count observationStartMJD

baseline10yrs r: Count observationStartMJD

big_sky_dust10yrs r: Count observationStartMJD

Variable Exposure Time

(Not recommended by SAC, but I'd already done it)

Adjust exposure time between 20 and 100s to get specified depth on every visit.

Images are shallower, but you get more of them. 2.9 million observations instead of 2.5, lose ~ 0.1 mag of final coadded depth.

Rolling Cadence

Even Years

Odd Years

We've run 13 different rolling variants

- 2,3,5,6,10 dec bands
- On/off maps and scrolling for full seasons
- 5, 10, 20% scale-down factors

Rolling Cadence

Start off normal, then
divide WFD in half and
alternate emphasis on
north and south

Year 1 like baseline,
WFD gets 120
observations/yr

Rolling, get 25 or 215
observations per year

mod2 night > 0 and night < 365: Count

mod2 night > 365 and night < 730: Count

mod2 night > 730 and night < 1095: Count

mod2 night > 1095 and night < 1461: Count

Can get extreme and have 6 declination stripes. 450+ observations in a season! (then 400 more observations spread over 9 years)

mod6 night > 0 and night < 365: Count

mod6 night > 365 and night < 730: Count

mod6 night > 730 and night < 1095: Count

mod6 night > 1095 and night < 1461: Count

Short exposures

- Mixing in 2s or 5s exposures

Twilight time

- Taking 1s exposures in twilight

Filter Loading

- Vary when u and z get swapped out of the camera

Alt-Sched like

- Y-band in twilight
- Blue filters in bright time
- Alternate north and south each night

very_alt3_rm5illum15_10yrs : Count observationStartMJD

very_alt3_rm5illum15_10yrs year 0-1: Hourglass

opsim night21: N visits alt az

opsim night22: N visits alt az

opsim night23: N visits alt az

opsim night24: N visits alt az

DDF

- Spatial Dithering
- DESC suggested cadence

Rotator Angle

Baseline keeps the camera-telescope angle near zero.

Can select a telescope angle per night to randomize orientation

Presto color

- g+i...40-120min later+g
- r+z...+r

presto_third_10yrs : Nvisits as function of Alt/Az

presto_third_10yrs year 1-2: Hourglass

Target of Opportunity

- 1, 10, 50, 100 alerts per year
- Usually able to detect ~55% of ToOs
